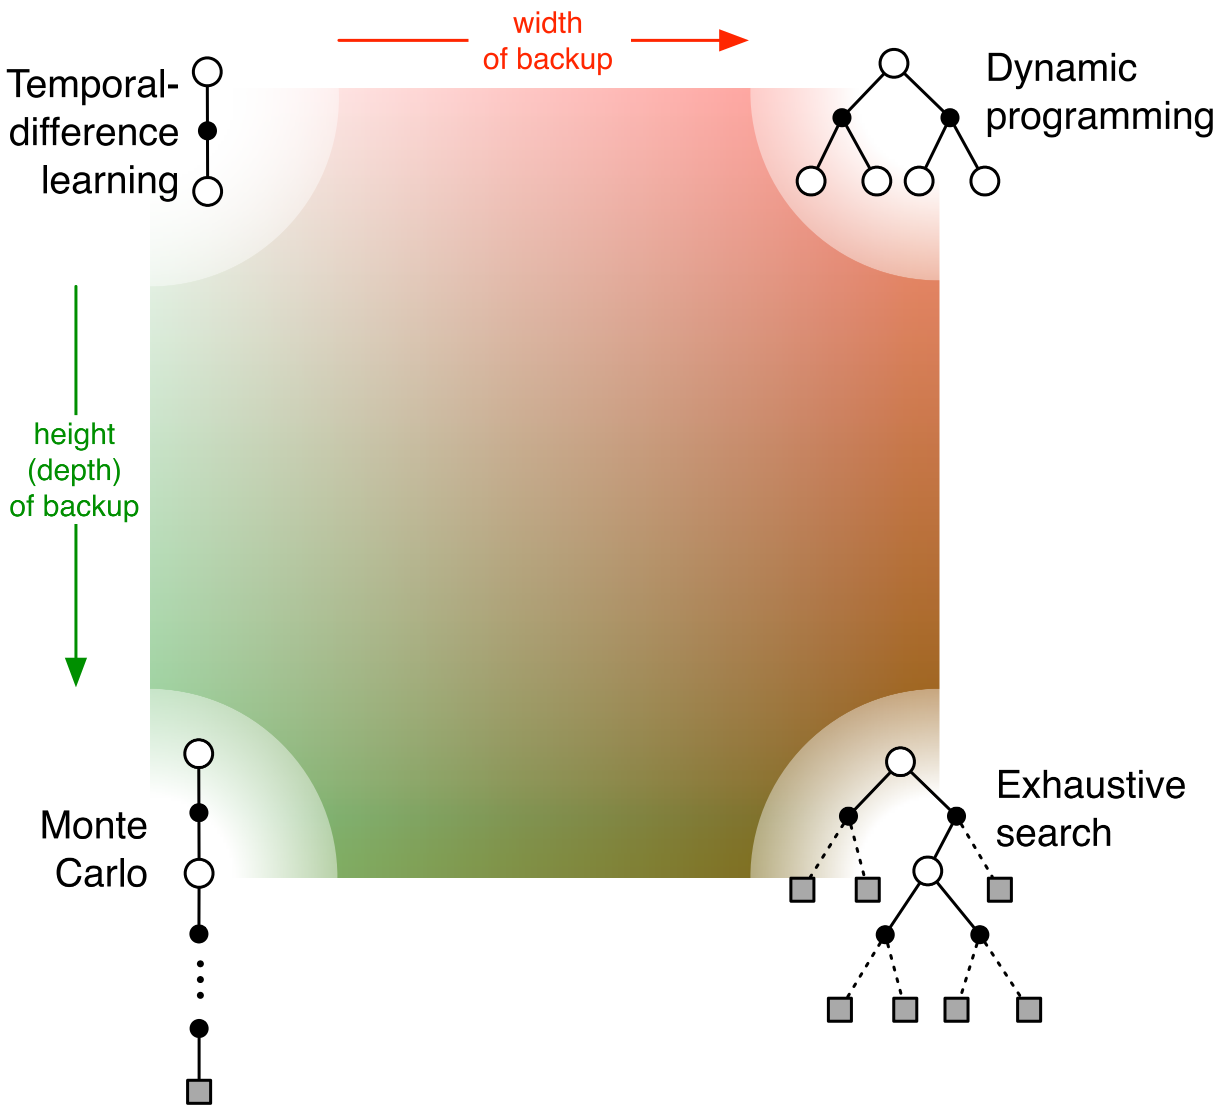
Unified View

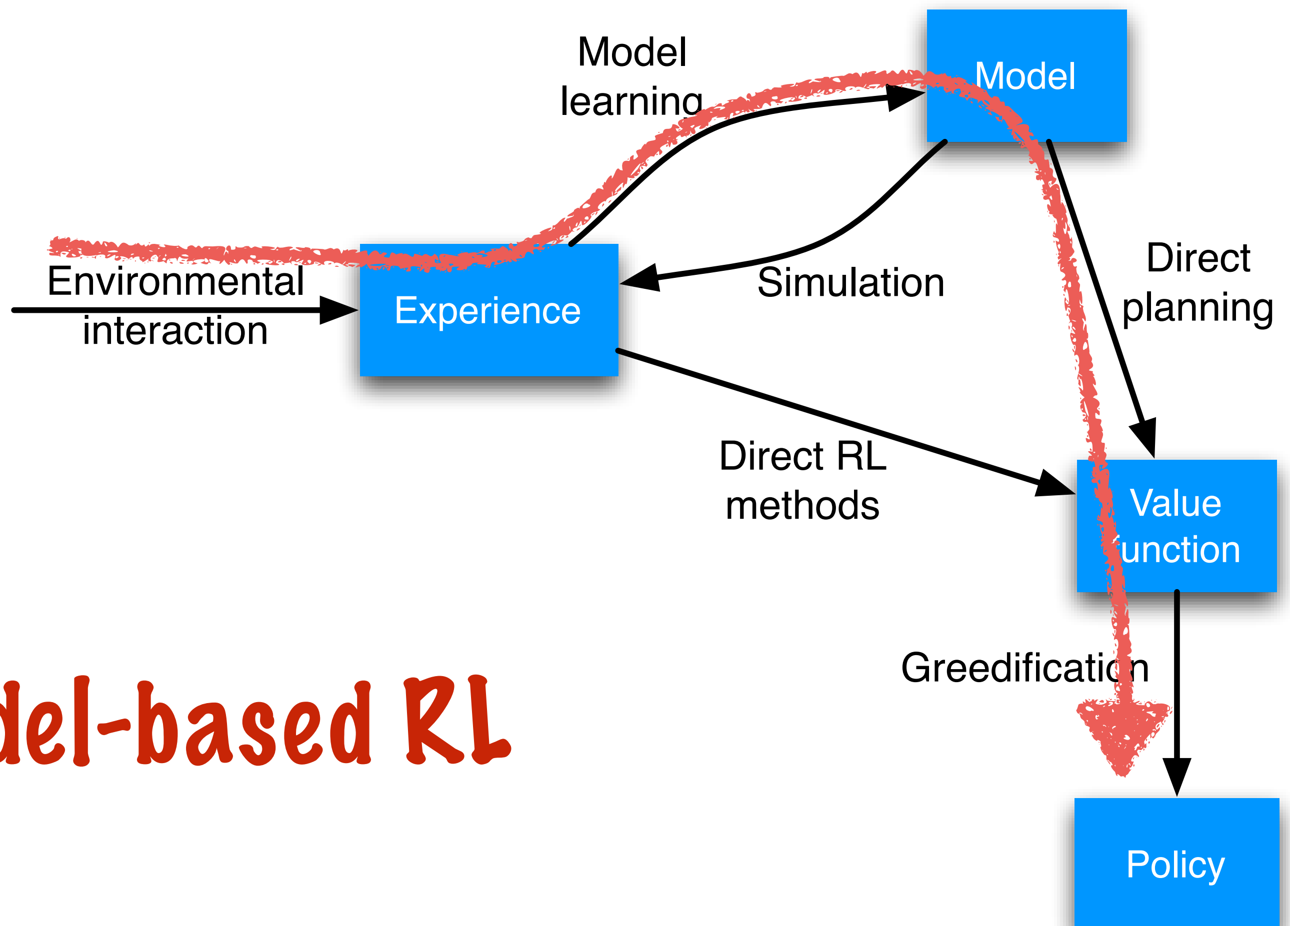


Chapter 8: Planning and Learning

Objectives of this chapter:

- To think more generally about uses of environment models
- Integration of (unifying) planning, learning, and execution
- “Model-based reinforcement learning”

Paths to a policy



Model-based RL

Models

- Model: anything the agent can use to predict how the environment will respond to its actions
- Distribution model: description of all possibilities and their probabilities
  - e.g., $\hat{p}(s', r \mid s, a)$ for all s, a, s', r
- Sample model, a.k.a. a simulation model
  - produces sample experiences for given s, a
  - allows reset, exploring starts
  - often much easier to come by
- Both types of models can be used to produce hypothetical experience

Planning

- Planning: any computational process that uses a model to create or improve a policy

$$\text{model} \xrightarrow{\text{planning}} \text{policy}$$

- Planning in AI:
  - state-space planning
  - plan-space planning (e.g., partial-order planner)
- We take the following (unusual) view:
  - all state-space planning methods involve computing value functions, either explicitly or implicitly
  - they all apply backups to simulated experience

$$\text{model} \longrightarrow \begin{array}{c}\text{simulated}\\ \text{experience}\end{array} \xrightarrow{\text{backups}} \text{values} \longrightarrow \text{policy}$$

Planning Cont.

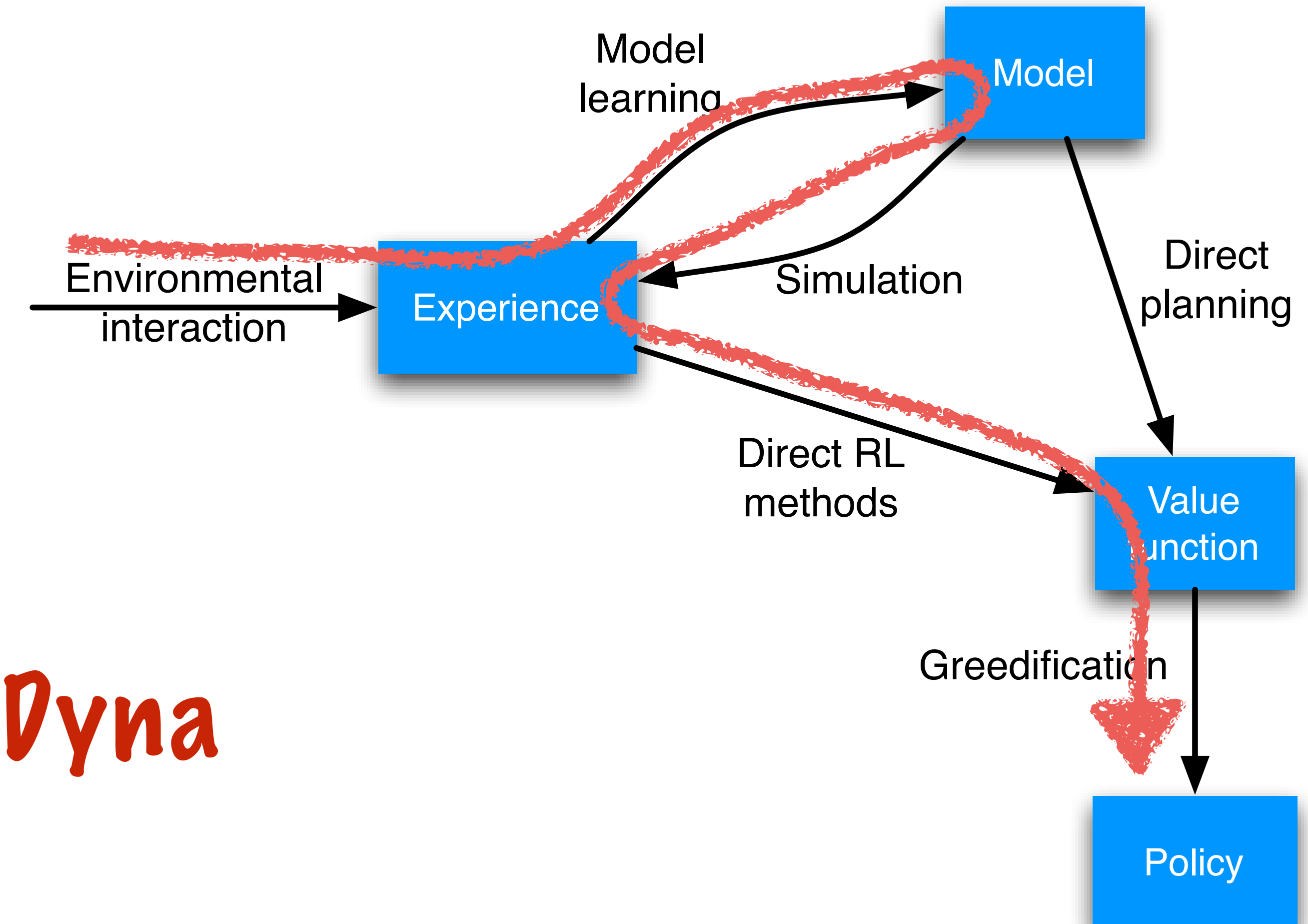
- Classical DP methods are state-space planning methods
- Heuristic search methods are state-space planning methods
- A planning method based on Q-learning:

Do forever:

1. Select a state, $S \in \mathcal{S}$, and an action, $A \in \mathcal{A}(s)$, at random
2. Send S, A to a sample model, and obtain
   a sample next reward, R, and a sample next state, S'
3. Apply one-step tabular Q-learning to S, A, R, S':
   $Q(S, A) \leftarrow Q(S, A) + \alpha[R + \gamma \max_a Q(S', a) - Q(S, A)]$

Random-Sample One-Step Tabular Q-Planning

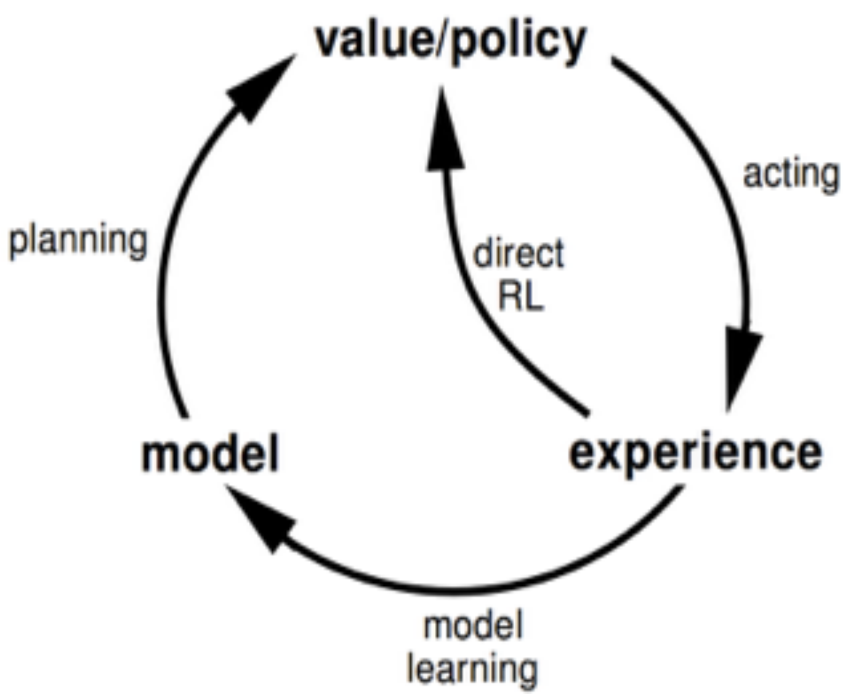
Paths to a policy



Dyna

Learning, Planning, and Acting

- Two uses of real experience:
  - model learning: to improve the model
  - direct RL: to directly improve the value function and policy
- Improving value function and/or policy via a model is sometimes called indirect RL. Here, we call it planning.



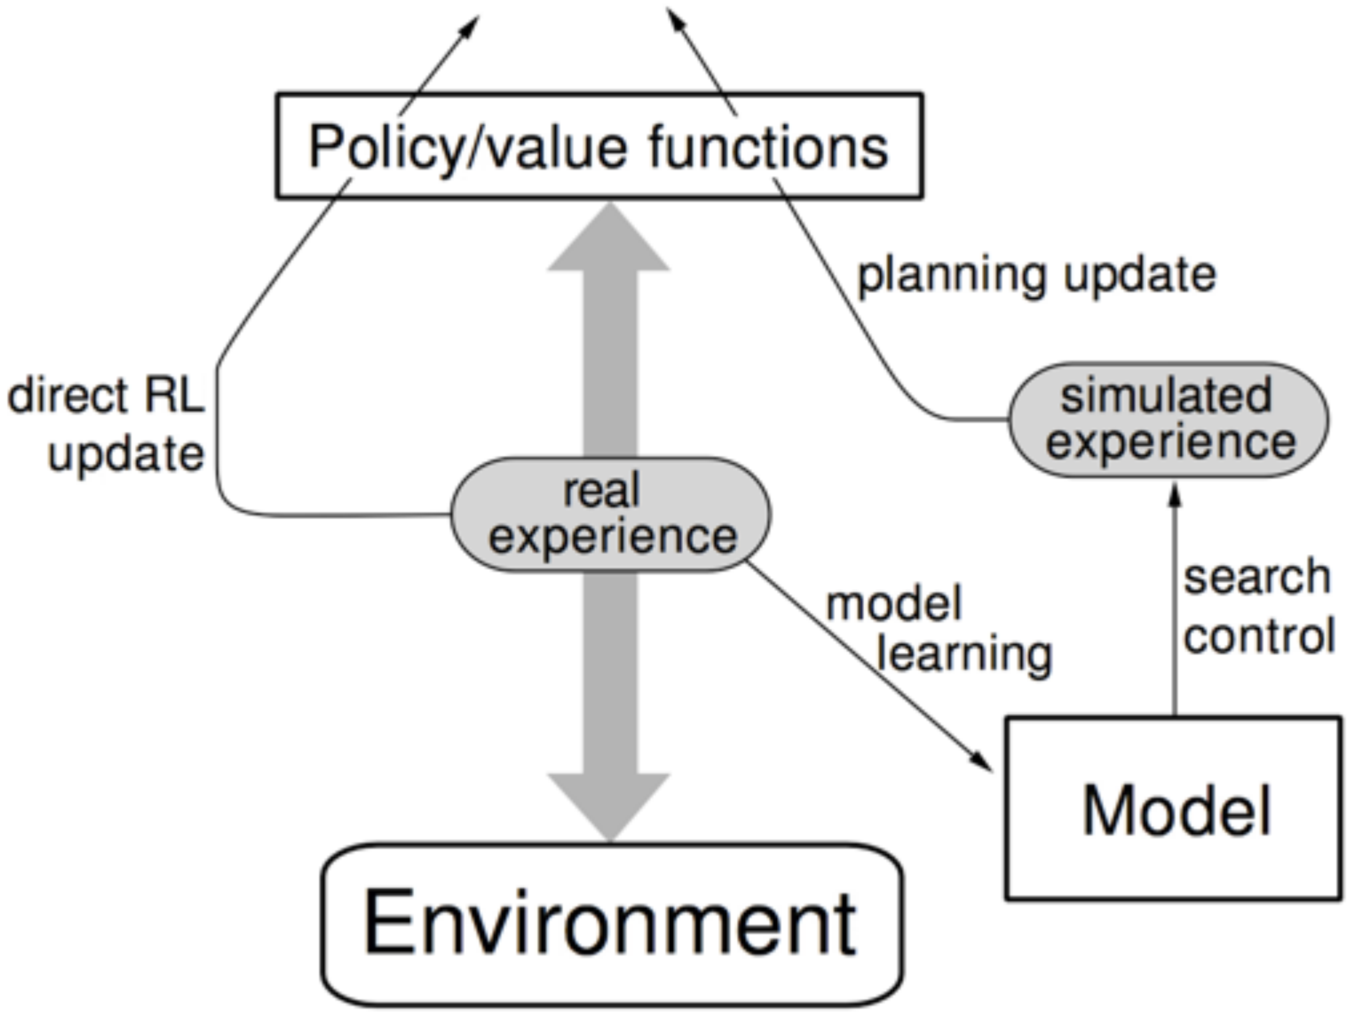
Direct (model-free) vs. Indirect (model-based) RL

- Direct methods
  - simpler
  - not affected by bad models
- Indirect methods:
  - make fuller use of experience: get better policy with fewer environment interactions

But they are very closely related and can be usefully combined:

planning, acting, model learning, and direct RL can occur simultaneously and in parallel

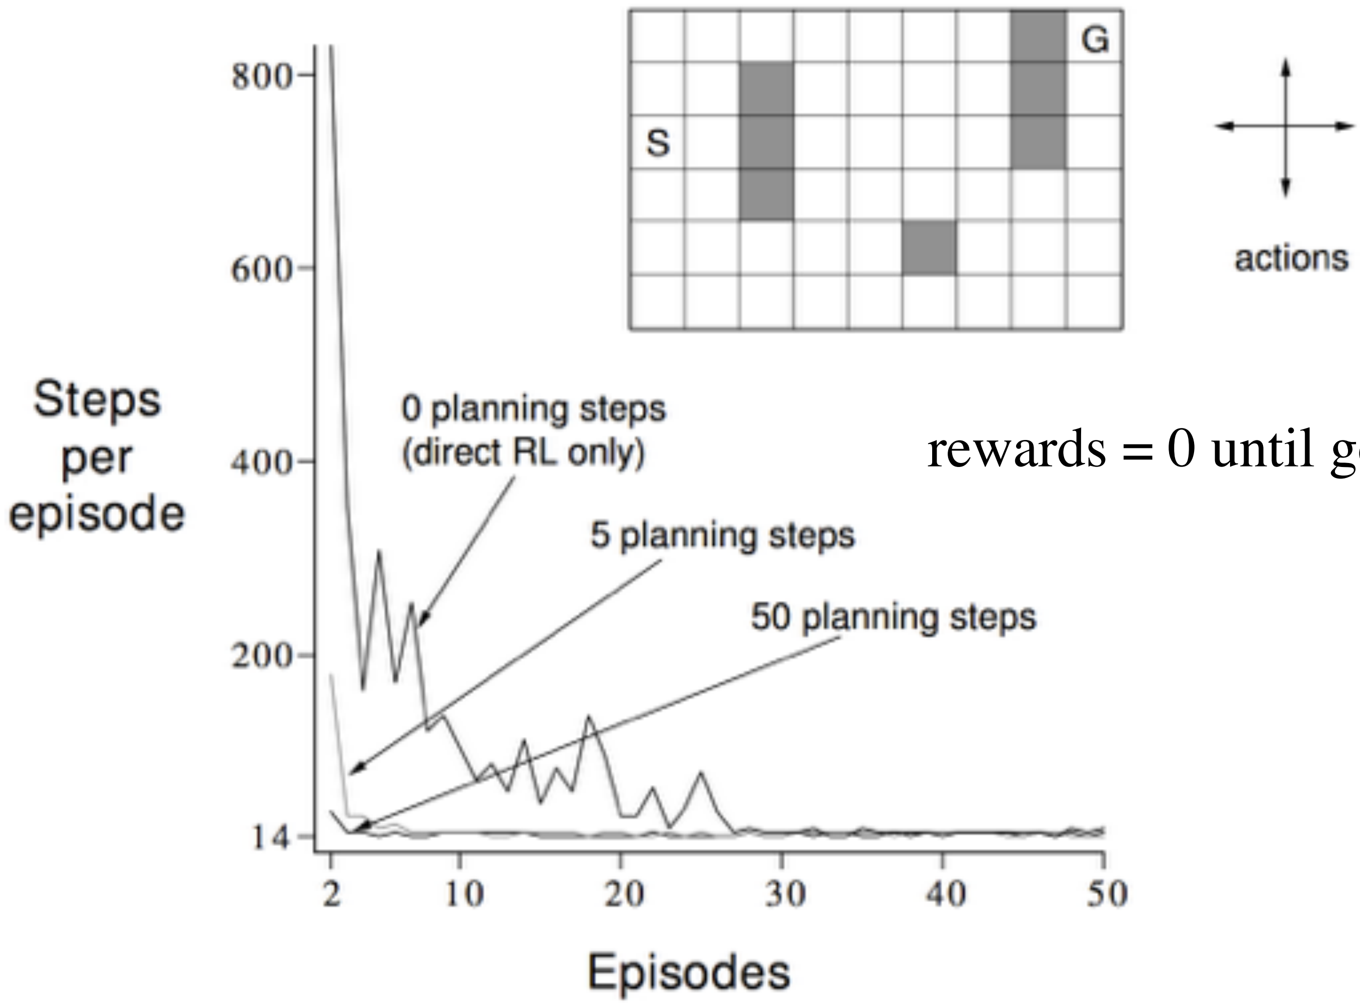
The Dyna Architecture



The Dyna-Q Algorithm

Initialize $Q(s,a)$ and $Model(s,a)$ for all $s \in \mathcal{S}$ and $a \in \mathcal{A}(s)$
Do forever:
- (a) $S \leftarrow$ current (nonterminal) state
- (b) $A \leftarrow \varepsilon$-greedy(S, Q)
- (c) Execute action A; observe resultant reward, R, and state, S'
- (d) $Q(S,A) \leftarrow Q(S,A) + \alpha[R + \gamma \max_a Q(S',a) - Q(S,A)]$ ← **direct RL**
- (e) $Model(S,A) \leftarrow R, S'$ (assuming deterministic environment) ← **model learning**
- (f) Repeat n times: ← **planning**
  - $S \leftarrow$ random previously observed state
  - $A \leftarrow$ random action previously taken in S
  - $R, S' \leftarrow Model(S,A)$
  - $Q(S,A) \leftarrow Q(S,A) + \alpha[R + \gamma \max_a Q(S',a) - Q(S,A)]$

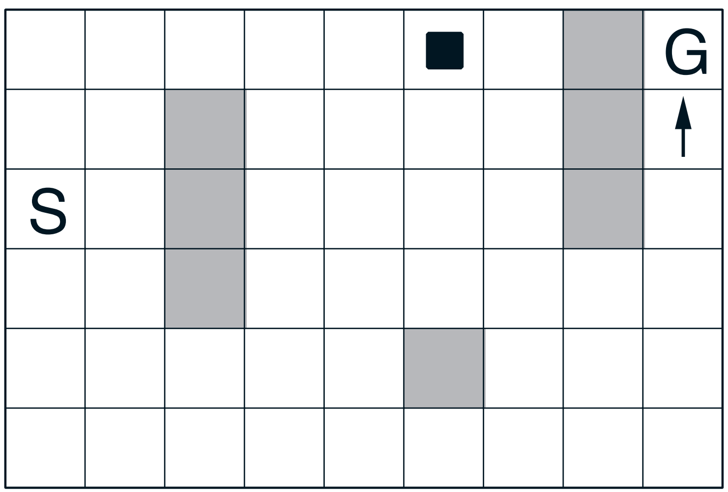
Dyna-Q on a Simple Maze



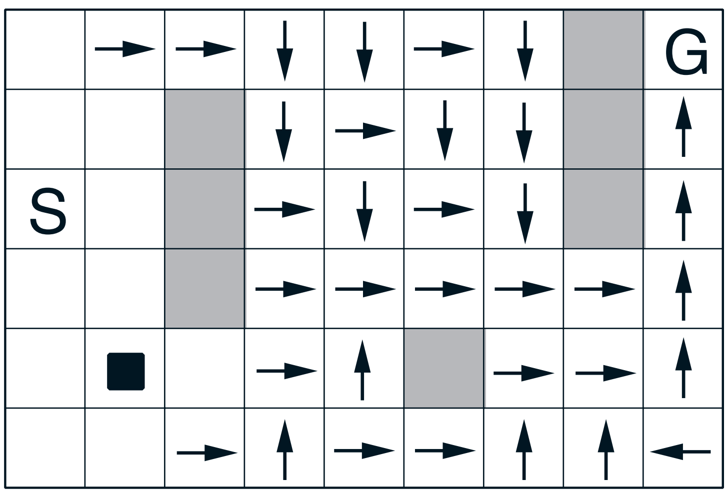
rewards = 0 until goal, when =1

Dyna-Q Snapshots: Midway in 2nd Episode

WITHOUT PLANNING (n=0)

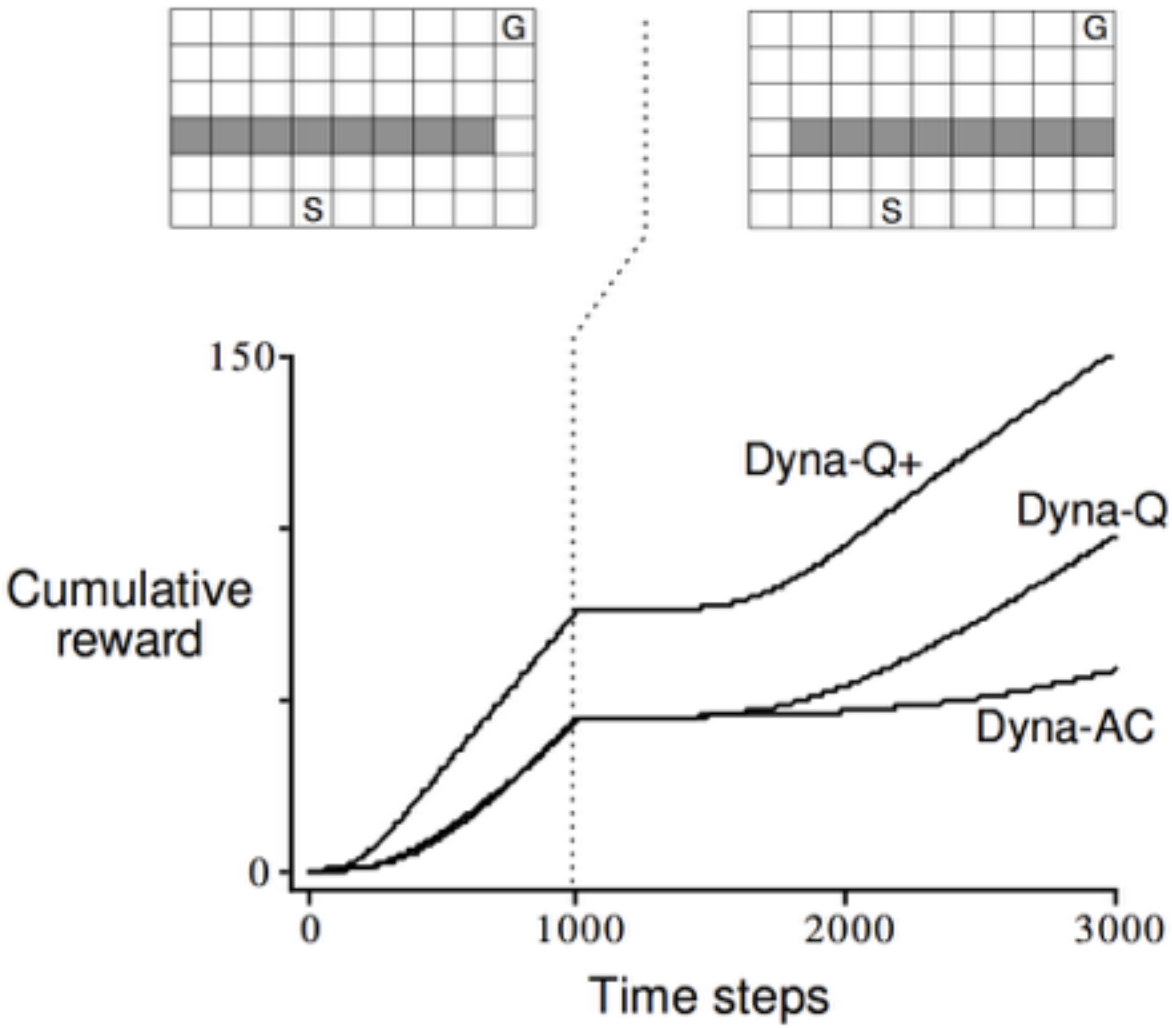


WITH PLANNING (n=50)



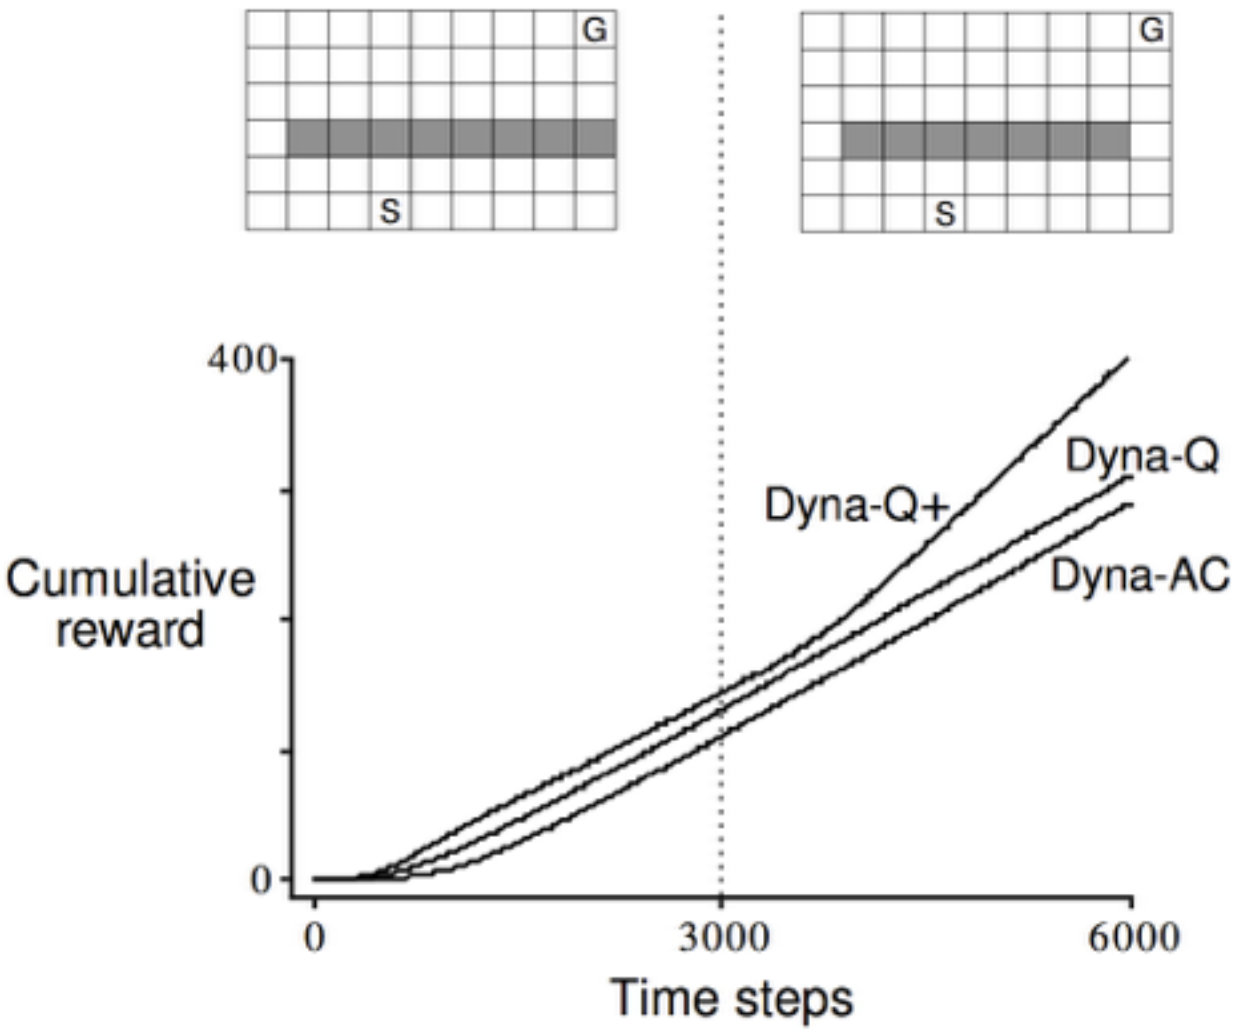
When the Model is Wrong: Blocking Maze

The changed environment is harder



When the Model is Wrong: Shortcut Maze

The changed environment is easier



What is Dyna-Q+?

- Uses an “exploration bonus”:
  - Keeps track of time since each state-action pair was tried for real
  - An extra reward is added for transitions caused by state-action pairs related to how long ago they were tried: the longer unvisited, the more reward for visiting

$$R + \kappa\sqrt{\tau}$$

time since last visiting the state-action pair

  - The agent actually “plans” how to visit long unvisited states

Prioritized Sweeping

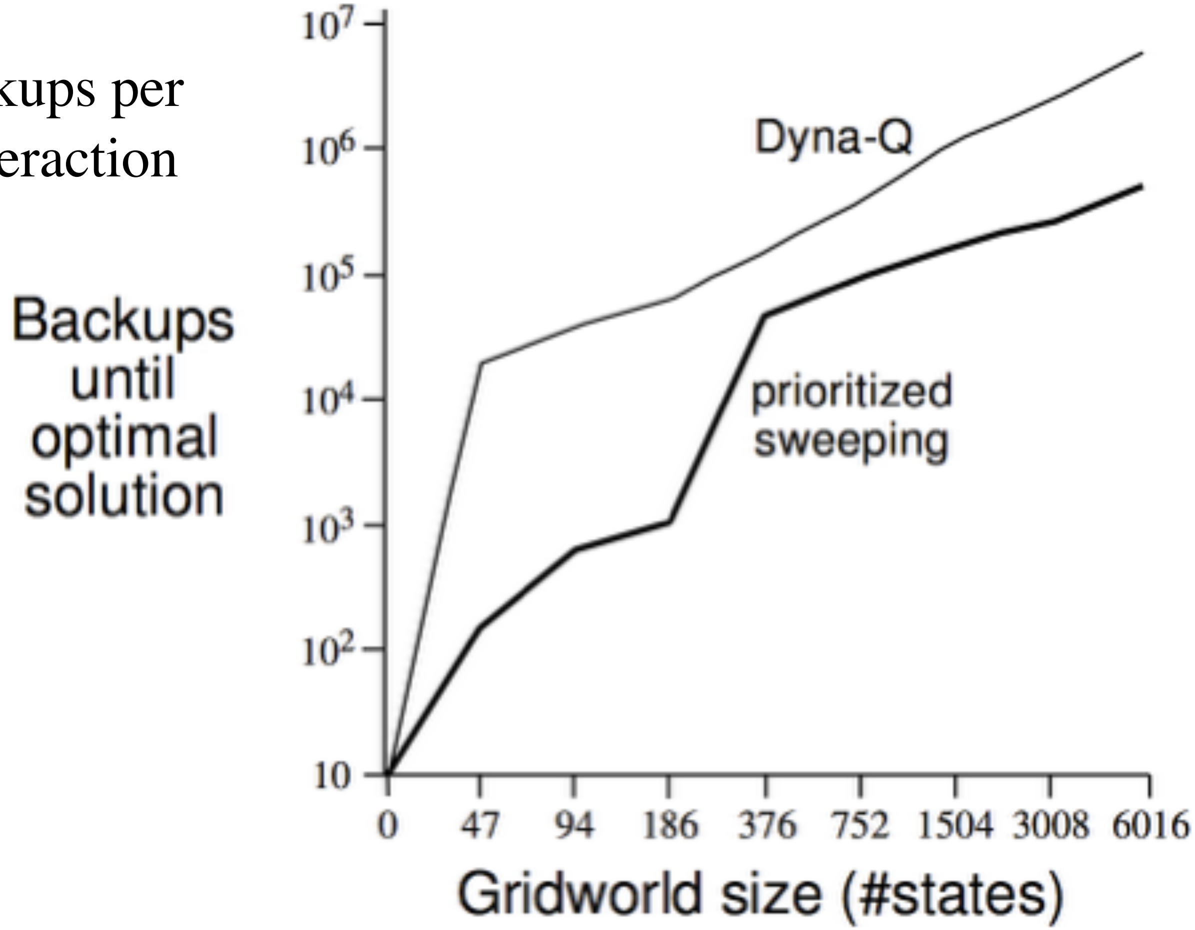
- Which states or state-action pairs should be generated during planning?
- Work backwards from states whose values have just changed:
  - Maintain a queue of state-action pairs whose values would change a lot if backed up, prioritized by the size of the change
  - When a new backup occurs, insert predecessors according to their priorities
  - Always perform backups from first in queue
- Moore & Atkeson 1993; Peng & Williams 1993
- improved by McMahan & Gordon 2005; Van Seijen 2013

Prioritized Sweeping

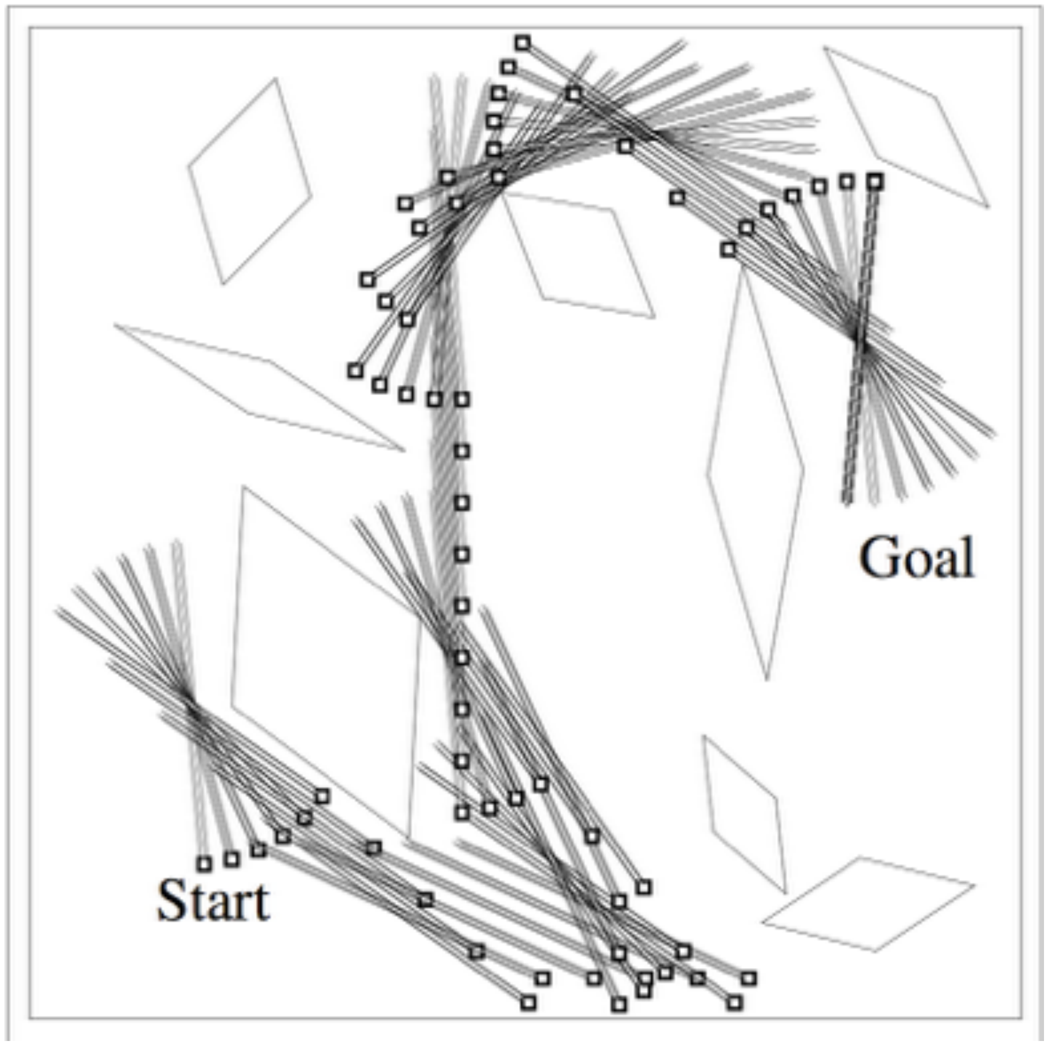
Initialize $Q(s,a)$, $Model(s,a)$, for all s,a, and $PQueue$ to empty
Do forever:
  (a) $S \leftarrow$ current (nonterminal) state
  (b) $A \leftarrow policy(S,Q)$
  (c) Execute action A; observe resultant reward, R, and state, S'
  (d) $Model(S,A) \leftarrow R, S'$
  (e) $P \leftarrow |R + \gamma \max_a Q(S',a) - Q(S,A)|$.
  (f) if $P > \theta$, then insert S,A into $PQueue$ with priority P
  (g) Repeat n times, while $PQueue$ is not empty:
    $S, A \leftarrow first(PQueue)$
    $R, S' \leftarrow Model(S,A)$
    $Q(S,A) \leftarrow Q(S,A) + \alpha[R + \gamma \max_a Q(S',a) - Q(S,A)]$
    Repeat, for all $\bar{S}, \bar{A}$ predicted to lead to S:
      $\bar{R} \leftarrow$ predicted reward for $\bar{S}, \bar{A}, S$
      $P \leftarrow |\bar{R} + \gamma \max_a Q(S,a) - Q(\bar{S},\bar{A})|$.
      if $P > \theta$ then insert $\bar{S}, \bar{A}$ into $PQueue$ with priority P

Prioritized Sweeping vs. Dyna-Q

Both use n=5 backups per environmental interaction



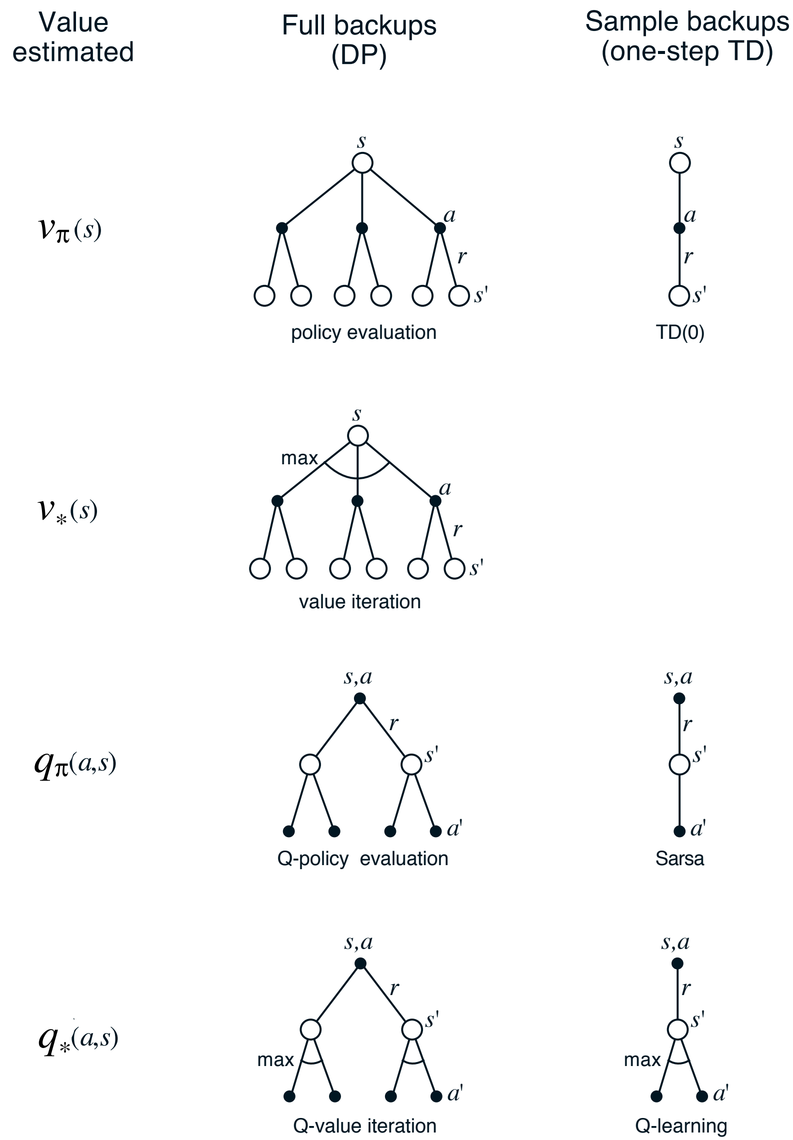
Rod Maneuvering (Moore and Atkeson 1993)



Improved Prioritized Sweeping with Small Backups

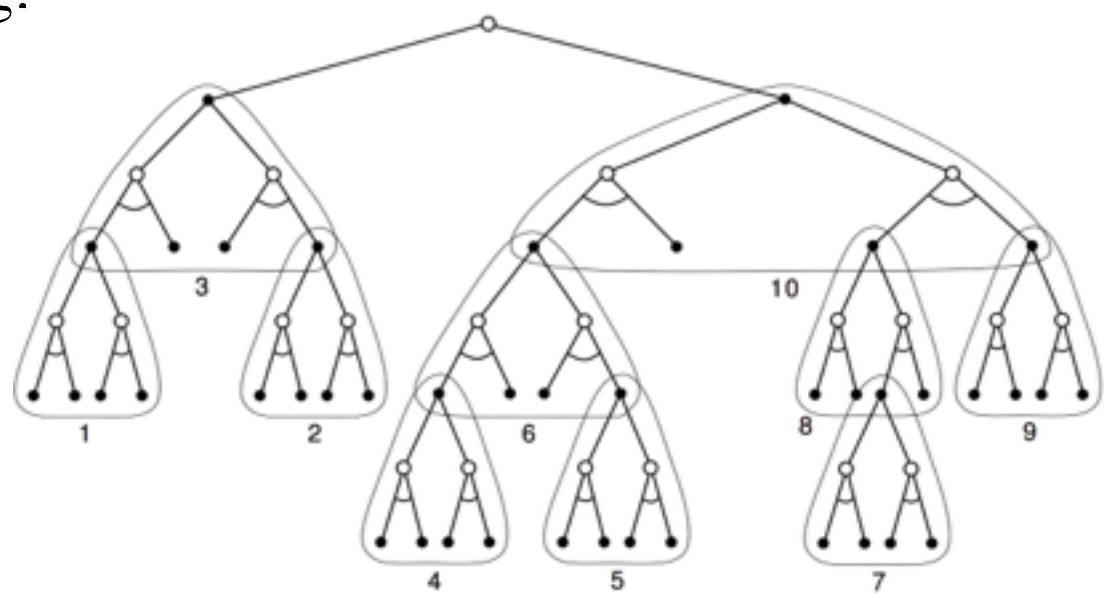
- Planning is a form of state-space search
  - a massive computation which we want to control to maximize its efficiency
- Prioritized sweeping is a form of search control
  - focusing the computation where it will do the most good
- But can we focus better?
- Can we focus more tightly?
- Small backups are perhaps the smallest unit of search work
  - and thus permit the most flexible allocation of effort

Full and Sample (One-Step) Backups



Heuristic Search

- Used for action selection, not for changing a value function (=heuristic evaluation function)
- Backed-up values are computed, but typically discarded
- Extension of the idea of a greedy policy — only deeper
- Also suggests ways to select states to backup: smart focusing:



Summary

- Emphasized close relationship between planning and learning
- Important distinction between distribution models and sample models
- Looked at some ways to integrate planning and learning
  - synergy among planning, acting, model learning
- Distribution of backups: focus of the computation
  - prioritized sweeping
  - small backups
  - sample backups
  - trajectory sampling: backup along trajectories
  - heuristic search
- Size of backups: full/sample/small; deep/shallow
